

Paper Replication: Measuring Cultural Dynamics through the Eurovision Song Contest

Group 13

Paula Nauta, Sudhang Shankar, Christoph Söls, Birgit Söser

Topic Motivation

- compare and extend paper with results of recent years [1]
- analyse relations between European countries based on voting behaviour
 - Measuring dynamics of cultures
 - Measuring subjective biases between pairs of countries
 - analyse whether other factors influence voting behaviour

Data

- Eurovision Voting Data from 2016 onwards
 - Jury- and Televotes separated
 - empirical Friend-or-Foe coefficient calculated from this data, for Jury- and Televoting respectively
- Varying parameters in ABMs
 - simulated points and Friend-or-Foe calculated per ABM

Research Question

Are Jury Voters less affected by Cultural Influences in Eurovision than
Tele Voters?

Agent-Based Model Description - Null Model

- Countries can freely give points to other countries - they are only assigning a fixed total amount of points
- Sum of scores is a fixed value (Matches total possible sum in Real voting)
- Assigned votes are chosen at random

Null model

For each voting country c_v :

1. For each competing country c_c :

- Sample $fit_v[c_c]$ from uniform distribution between 0 and 1

2. For each competing country c_c :

- Assign $p_{v,c} = 58 * \frac{fit_v[c_c]}{\sum_c fit_v[c]}$

[1]

Agent-Based Model Description - Model 1

- Countries are allowed to give fixed scores (12, 10, 8, 7, 6, 5, 4, 3, 2, 1)
- Follows the rules of Eurovision
- The assignment of points is not influenced by anything else

Model 1

scores = [12, 10, 8, 7, 6, 5, 4, 3, 2, 1]

For each voting country c_v :

1. For each competing country c_c :

- Sample $fit_v[c_c]$ from uniform distribution between 0 and 1

2. For each competing country c_c :

- If $rank(fit_v[c_c]) \leq 10$: assign $p_{v,c} = scores[rank(fit_v[c_c])]$
- Else: assign $p_{v,c} = 0$

[1]

Agent-Based Model Description - Affinity Model

- Countries are allowed to give fixed scores (12, 10, 8, 7, 6, 5, 4, 3, 2, 1)
- Each “vote” has a “quality” part (q) and,
- a culture part in the form of a **cultural Affinity Network**
 - Nodes are voting countries
 - Edge weights are from a normal distribution with variable μ and σ
- Alpha determines the importance of either part

Affinity Model

scores = [12, 10, 8, 7, 6, 5, 4, 3, 2, 1]

w = affinity network

For each competing country c_c :

- sample $q[c_c]$ from empirical s'_c distribution

For each voting country c_v :

1. For each competing country c_c :

- assign $fit_v[c_c] = \alpha q[c_c] + (1 - \alpha)w_{v,c}$

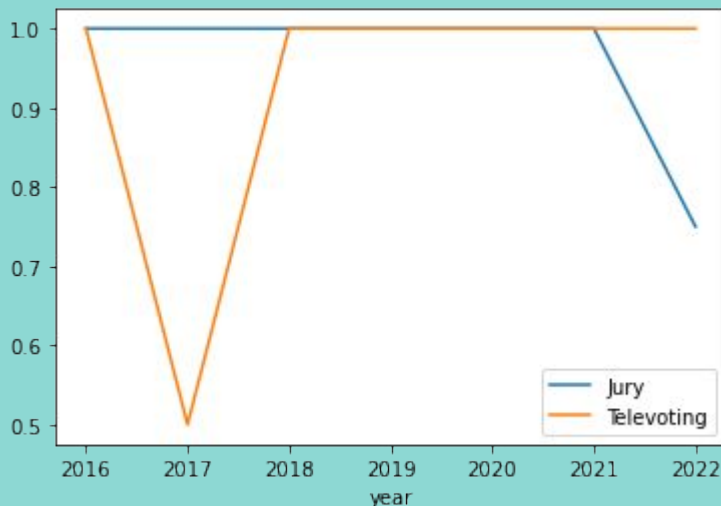

2. For each competing country c_c :

- If $rank(fit_v[c_c]) \leq 10$: assign $p_{v,c} = scores[rank(fit_v[c_c])]$
- Else: assign $p_{v,c} = 0$

Agent-Based Model Description - Affinity Model - Objectivity Parameter

- “Objectivity” in voting parameter: Alpha
 - Low alpha => Low Objectivity => Higher influence of Culture
- Unlike the 2013 paper, we vary alpha (because we have separate Jury and Televoting data)
 - However, results are inconclusive: **We cannot say Jury voters are more objective**
 - **It seems that both Jury and Tele-Voters are essentially objective (high alpha)**
 - Year 2022 gives counter-intuitive results!

Model Analysis - 2016

- Params causing minimum Kolmogorov-Smirnov selected
- Plotted and compared visually with the empirical FoF

Year: 2016, Jury Voters

Year: 2016, Tele Voters

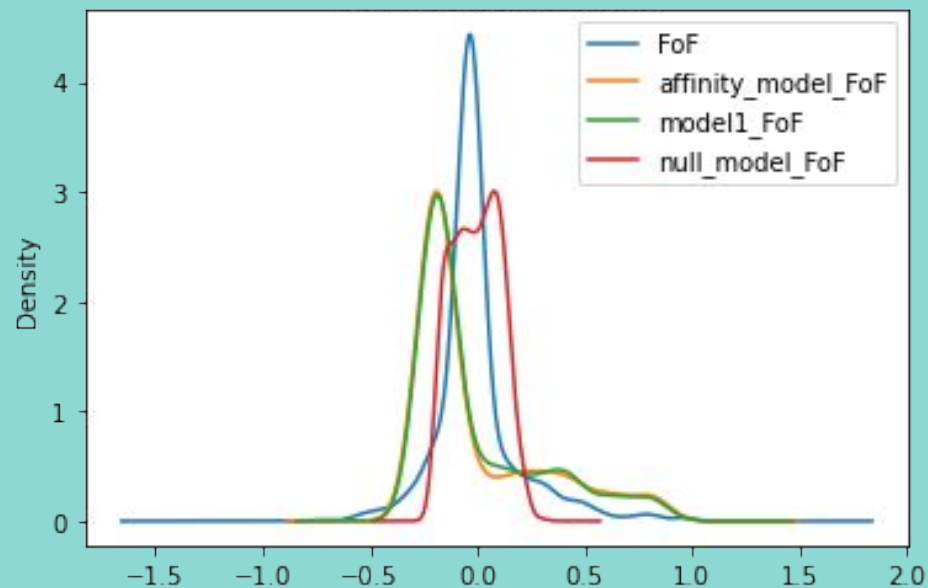

Model Analysis - 2017

Year: 2017, Jury Voters

Year: 2017, Tele Voters

Model Analysis - 2018

Year: 2018, Jury Voters

Year: 2018, Tele Voters

Model Analysis - 2019

Year: 2019, Jury Voters

Year: 2019, Tele Voters

Model Analysis - 2021

Year: 2021, Jury Voters

Year: 2021, Tele Voters

Model Analysis - 2022

Year: 2022, Jury Voters

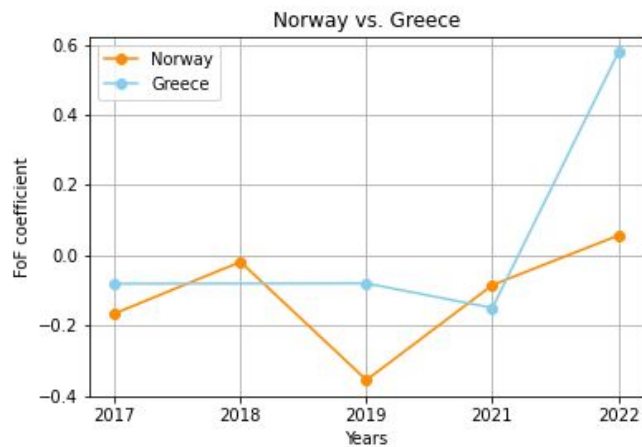

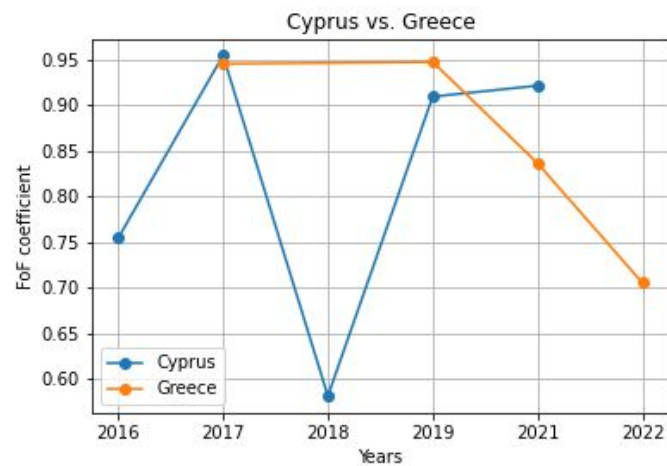

Year: 2022, Tele Voters

Model Analysis

- Computing FoF coefficient and analysing how well respective countries get along with each other
- Analysing EU-15 countries with the respective FoF coefficient
- (Note: EU-15 are EU member countries prior to 1 May 2004)

2016

Brussels bombing (BEL), Böhmermann affair (GER), VW skandal (GER)

2017

Brexit (GBR), Asylum-Policy (AUT)

2018

Independence of Catalonia (ESP), VW skandal (again) (GER)

2019

FFF (SWE), fire in Notre-Dame (FRA)

2021

Covid (everywhere)

2022

War (UKR)

Conclusions

- The RQ cannot be answered conclusively
 - There are major fluctuations across years
 - We expected consistently lower values of alpha for Tele voters and higher values of alpha for Jury voters

Limitations

- The linear affinity model seems to be too simple
 - The voting is not random
- Only 6 years' data points were used
- More granular variations of μ , σ and α should be applied in future work
